

## Quiz 4

[Help](#)

The **due date** for this quiz is **Sun 31 Aug 2014 4:30 PM PDT**.

- ☐ In accordance with the Coursera Honor Code, I (Dan Nuttle) certify that the answers here are my own work.

### Question 1

Consider the space shuttle data `?shuttle` in the `MASS` library. Consider modeling the use of the autolander as the outcome (variable name `use`). Fit a logistic regression model with autolander (variable `auto`) use (labeled as "auto" 1) versus not (0) as predicted by wind sign (variable `wind`). Give the estimated odds ratio for autolander use comparing head winds, labeled as "head" in the variable `headwind` (numerator) to tail winds (denominator).

- ☐ 0.031
- ☐ -0.031
- ☐ 1.327
- ☐ 0.969

### Question 2

Consider the previous problem. Give the estimated odds ratio for autolander use comparing head winds (numerator) to tail winds (denominator) adjusting for wind strength from the variable `magn`.

- ☐ 0.684
- ☐ 1.485
- ☐ 0.969
- ☐ 1.00

### Question 3

If you fit a logistic regression model to a binary variable, for example use of the autolander, then fit a logistic regression model for one minus the outcome (not using the autolander) what happens to the coefficients?

- ☐ The coefficients change in a non-linear fashion.
- ☐ The coefficients get inverted (one over their previous value).
- ☐ The intercept changes sign, but the other coefficients don't.
- ☐ The coefficients reverse their signs.

### Question 4

Consider the insect spray data `InsectSprays`. Fit a Poisson model using spray as a factor level. Report the estimated relative rate comparing spray A (numerator) to spray B (denominator).

- ☐ 0.9457
- ☐ 0.321
- ☐ 0.136
- ☐ -0.056

### Question 5

Consider a Poisson glm with an offset,  $t$ . So, for example, a model of the form `glm(count ~ x + offset(t), family = poisson)` where  $x$  is a factor variable comparing a treatment (1) to a control (0) and  $t$  is the natural log of a monitoring time. What is impact of the coefficient for  $x$  if we fit the model `glm(count ~ x + offset(t2), family = poisson)` where  $t2 <- \log(10) + t$ ? In other words, what happens to the coefficients if we change the units of the offset variable. (Note, adding  $\log(10)$  on the log scale is multiplying by 10 on the original scale.)

- ☐ The coefficient estimate is divided by 10.
- ☐ The coefficient estimate is unchanged
- ☐ The coefficient is subtracted by  $\log(10)$ .
- ☐ The coefficient estimate is multiplied by 10.

## Question 6

Consider the data

```
x <- -5:5
y <- c(5.12, 3.93, 2.67, 1.87, 0.52, 0.08, 0.93, 2.05, 2.54, 3.87, 4.97)
```

Using a knot point at 0, fit a linear model that looks like a hockey stick with two lines meeting at  $x=0$ . Include an intercept term,  $x$  and the knot point term. What is the estimated slope of the line after 0?

- ☐ -1.024
- ☐ -0.183
- ☐ 2.037
- ☐ 1.013
